Data Structures and Algorithms

Laboratory 07

Doubly Linear Linked List

Version: 1.0.0

Release Date: 05-11-2023

Department of Information Technology University of the Punjab Lahore, Pakistan

Contents:

- Learning Objectives
- Required Resources
- General Instructions
- Background and Overview
 - o Pointers and Dynamic Memory Allocation
 - Self-Referential Objects
 - Representation
 - Implementation
 - o Doubly LinkedList
 - Insert Node
 - Delete Node
- Activities
 - Pre-Lab Activity
 - Task 01: Doubly LinkedList Implementation
 - o In-Lab Activity
 - Task 01: Add Functions to LinkedList
 - Task 02: Sort LinkedList
 - Post-Lab Activity
 - Task 01: Reverse LinkedList
- Submissions
- References and Additional Material
- Lab Time and Activity Simulation Log

Learning Objectives:

- Pointers and Dynamic Memory Allocation
- Self-Referential Objects
- Doubly LinkedList

Resources Required:

- Desktop Computer or Laptop
- Microsoft ® Visual Studio 2022

General Instructions:

- In this Lab, you are **NOT** allowed to discuss your solution with your colleagues, even not allowed to ask how is s/he doing, this may result in negative marking. You can **ONLY** discuss with your Teaching Assistants (TAs) or Lab Instructor.
- Your TAs will be available in the Lab for your help. Alternatively, you can send your queries via email to one of the followings.

Teachers:					
Course Instructor	Prof. Dr. Syed Waqar ul Qounain	swjaffry@pucit.edu.pk			
Lab Instructor	Madiha Khalid	madiha.khalid @pucit.edu.pk			
	Muhammad Nabeel	bitf20m009@pucit.edu.pk			
Teacher Assistants	Abdul Rafay Zubairi	bcsf20a032@pucit.edu.pk			

Background and Overview

Pointers and Dynamic Memory Allocation

Pointers and dynamic memory allocation are important concepts in programming, particularly in languages like C and C++. Pointers allow you to work with memory addresses, while dynamic memory allocation allows you to manage memory at runtime.

Pointers:

A pointer is a variable that stores the memory address of another variable. It allows you to indirectly access the value of the variable stored at that address. Pointers are often used for various purposes, such as dynamically allocated memory, working with arrays, and passing functions as arguments.

```
1
       #include <iostream>
 2
 3
      ⊡int main() {
 4
           int x = 10;
           int* ptr; // Declare a pointer to an int
 5
 6
           ptr = &x; // Assign the memory address of x to ptr
 7
            std::cout << "The value of x: " << x << std::endl;</pre>
 8
 9
           std::cout << "The value pointed to by ptr: " << *ptr << std::endl;</pre>
10
           *ptr = 20; // Modify the value through the pointer
11
            std::cout << "The updated value of x: " << x << std::endl;</pre>
12
13
           return 0;
14
15
       }
16
```

Figure 1(Pointers)

Explanation:

In this example, ptr is a pointer to an integer, and it is assigned the memory address of the variable x. You can access and modify the value of x through the pointer using the dereference operator (*ptr).

```
Select Microsoft Visual Studio Debug Console
The value of x: 10
The value pointed to by ptr: 10
The updated value of x: 20
```

Figure 2(Output)

Dynamic Memory Allocation

Dynamic memory allocation allows you to allocate memory for variables at runtime. In C++, you can use new and delete operators to allocate and deallocate memory for objects on the heap.

```
1
       #include <iostream>
 2
 3

_ int main() {

            int* dynamicArray = new int[5]; // Allocate an array of 5 integers
 4
 5
            for (int i = 0; i < 5; i++) {</pre>
 6
 7
                dynamicArray[i] = i * 10;
 8
            Ż
 9
            for (int i = 0; i < 5; i++) {</pre>
10
                std::cout << "dynamicArray[" << i << "] = " << dynamicArray[i] << std::endl;</pre>
11
            Ż
12
13
            delete[] dynamicArray; // Deallocate the memory
14
15
16
            return 0;
       }
17
```

Figure 3(Dynamic Memory Allocation)

Explanation:

In this example, dynamicArray is allocated on the heap with space for 5 integers. After using it, it is essential to deallocate the memory using delete[] to prevent memory leaks.

Note: In modern C++ (C++11 and later), it is recommended to use smart pointers like std::unique_ptr and std::shared_ptr for better memory management, as they automatically handle memory deallocation.

dynamicArray[0] = 0 dynamicArray[1] = 10 dynamicArray[2] = 20 dynamicArray[3] = 30 dynamicArray[4] = 40

Figure 4(Output)

Deallocation of Memory:

Memory should be properly deallocated. In case of not properly deallocating memory, every time your program run causes memory leak that is very critical problem.

```
3
     ⊡int main()
4
       {
5
           int**** ptr = new int***;
           *ptr = new int**;
6
           **ptr = new int*;
7
           ***ptr = new int;
8
9
           ****ptr = 10;
           cout << ****ptr << endl;</pre>
10
11
```

Figure 5(Multiple indirection)

Explanation:

In above example a **ptr** is pointer and its type is pointer to pointer to pointer to integer. Output of above code is below

10

Figure 6(Output)

Deallocation of memory should be done properly.

```
11 delete*** ptr;
12 delete** ptr;
13 delete* ptr;
14 delete ptr;
15 ptr = nullptr; // avoid dangling pointer
16 3
```

Figure 7(Deallocation)

Self-Referential Objects:

Classes that have capability to refer to their own types of objects are called **Self Referential Classes/Structs.** Objects of such classes are called self-referential Objects.

Self-referential structure in C++ are those structure that contains one or more than one pointer as their member which will be pointing to the structure of the same type. In simple words, a structure that is pointing to the structure of the same type is known as a self-referential structure.

Figure 8(Self Referential Objects)

Explanation:

In Figure 8 we have declared a struct Node. It has three data members info, next and prev;

Info Represents the information data part. Enables the object to store relevant information in it. There can be more than one identifier of same/different datatypes depending upon the application /situation.

next and prev Represent the link part. Enables the object to a self-referential object. There can be more than one such references used for different purposes in different applications /situations.

```
int main()
 9
10
       {
11
12
           Node a, b,c, d, e; // allocated on stack memory portion;
           a.info = 1;
13
           b.info = 2;
14
           c.info = 3;
15
           d.info = 4:
16
17
           e.info = 5:
18
           cout << a.info << " " << b.info << " " << c.info << " " << d.info << " " << e.info << endl;
19
```

Figure 9(Node objects)

Explanation:

At line 12 we have declared five Node objects and next lines we have initialized their info data members with proper values. At line 18 we have displayed them.

```
Select Microsoft Visual Studio Debug Console
1 2 3 4 5
```

Figure 10(Output)

20	a.next = &b
21	b.next = &c
22	c.next = &d
23	d.next = &e
24	b.prev = &a
25	c.prev = &b
26	d.prev = &c
27	e.prev = &d
28	e.next = a.prev = nullptr;

Figure 11(Double Link)

Explanation:

In Figure 11 we have initialized each Node next and previous pointer with the addresses of other nodes such that each node can refers a same node in sequence to a next node as well as previous Node.

```
29 Node* head = &a;
30 cout << "a : " << a.info << endl;
31 cout << "b : " << a.next->info << endl;
32 cout << "c : " << a.next->next->info << endl;
33 cout << "d : " << a.next->next->info << endl;
34 cout << "e : " << a.next->next->next->info << endl;
35 }
```

Figure 12(Double Links)

Output:

1	G Select Microsoft Visual Studio Debug Console						
а	:	1					
ь	:	2					
с	:	3					
d	:	4					
e	:	5					

Figure 13(Output)

```
30
30
30
cout << "a : " << e.prev->prev->prev->info << endl;
31
cout << "b : " << e.prev->prev->info << endl;
32
cout << "c : " << e.prev->prev->info << endl;
33
cout << "d : " << e.prev->info << endl;
34
cout << "e : " << e.info << endl;
35
}</pre>
```

Figure 14(Previous Link)

Explanation:

In Figure 14 we have access info of a,b,c,d and e nodes through previous links of each node. This is the facility of Double links.

Some Interesting Scenarios:

```
36 Node* head = &a;
37 cout << head->next->next->prev->next->prev->info << endl;
38 head->next->next->prev->next->info = head->next->next->prev->next->info;
39 cout << head->next->next->prev->next->info << endl;
40 cout << (*(*((*head).next)).next->prev->next).info << endl;
41
42
```

Figure 15(Doubly Link)

Doubly Linear LinkedList

A doubly linked list is a data structure used in computer science and programming for organizing and storing a collection of elements. It is similar to a singly linked list, but with a key difference: each node in a doubly linked list contains not only a reference to the next node (like in a singly linked list) but also a reference to the previous node. This bidirectional linkage allows for more versatile operations compared to a singly linked list.

Here are the key characteristics of a doubly linked list:

 Nodes: Each element in a doubly linked list is stored in a node. Each node contains data and two references or pointers: one pointing to the next node in the list (often called "next" or "forward" pointer), and the other pointing to the previous node (often called "prev" or "backward" pointer).

Figure 16(Double LinkedList)

- 2. **Traversal:** You can traverse a doubly linked list in both directions, forward and backward, using the next and prev pointers. This makes it more flexible for certain operations that require moving in both directions, such as inserting or deleting elements.
- 3. **Insertion and Deletion:** Inserting and deleting nodes in a doubly linked list is generally more efficient than in a singly linked list because you can access the previous node directly. In a singly linked list, to delete a node, you often need to traverse the list from the beginning to find the previous node, which takes O(n) time in the worst case. In a doubly linked list, this can be done in O (1) time.

Doubly linked lists are commonly used in scenarios where efficient insertions and deletions are required, and you need bidirectional traversal, such as in certain types of data structures like doubleended queues (deque) or when implementing certain algorithms like LRU (Least Recently Used) caches. However, they require more memory than singly linked lists due to the additional backward pointers for each node.

```
2 Class Node {
3     public:
4         int data;
5         Node* prev;
6         Node* next;
7         Node(int val) : data(val), prev(nullptr), next(nullptr) {}
9     };
```

Figure 17(Doubly LinkedList Node)

Explanation:

At Line 2 we have declared a class Node. It has data, prev and next node.

```
⊡int main()
11
12
       {
            Node* head = new Node(10);
13
            head->next = new Node(20);
14
15
            head->prev = nullptr;
           head->next->prev = head;
16
            cout << head->data << endl; // 10</pre>
17
            cout << head->next->data << endl; //20;</pre>
18
            cout << head->next->prev->next->data << endl; //20</pre>
19
            cout << head->next->prev->data << endl; //10</pre>
20
21
22
            delete head->next;
            delete head;
23
24
            head = nullptr;
25
26
       3
```

Figure 18(Insertion in LinkedList)

Activities

Pre-Lab Activities:

Task 01: Doubly Singly LinkedList implementation

Declare these two classes and add public function definition and implementations for a working doubly linear linkedlist.

```
// forward declaration of template class List
template<class T>
class DList;
template<class T>
class DNode
{
        friend DList<T>;
        T info;
        DNode<T>* next;
        DNode<T>* prev;
        // Methods...
};
template<class T>
class DList
{
        DNode<T>* head;
        DNode<T>* tail;
        // Public member functions...
};
```

Implement following functions for List class.

- 1. Constructor, destructor, Copy-constructor.
- 2. void insertAtHead(T value)
- 3. void insertAtTail(T value)
- 4. **bool deleteAtHead()**
- 5. bool deleteAtTail()
- 6. **void printList()**

In-Lab Activities

Task 01 Add member Function

Add these members function to Doubly LinkedList class

1. DNode* getNode(int n)

This function should return pointer to nth node in the list. Returns last node if n is greater than the number of nodes present in the list.

2. bool insertAfter(T value, T key)

Insert a node after some node whose info equals input parameter key and returns true if node is successfully inserted, false otherwise.

3. bool insertBefore(T value, T key)

Insert a node before some node whose info equals input parameter key and returns true if node is successfully inserted, false otherwise.

4. bool deleteBefore(T key)

Delete a node that is before some node whose info equals input parameter key and returns true if node is successfully inserted, false otherwise. Check boundary cases i.e if node to be deleted is last node or first node in the list.

5. bool deleteAfter(T value)

Delete a node that is after some node whose info equals input parameter key and returns true if node is successfully inserted, false otherwise. Check boundary cases i.e if node to be deleted is last node or first node in the list.

6. int getLength()

Returns the total number of nodes in the list.

7. DNode* search(T x)

Search a node with value "x" from list and return its link. If multiple nodes of same value exist, then return pointer to first node having the value "x".

Task 02 Sort Doubly LinkedList

1. void sort ()

Add this member function to the LinkedList class. This function sorts the nodes of the linked list in ascending order (w.r.t. the "data" present in each node). Keep the following things in mind when implementing this function:

- When sorting the linked list, you are NOT allowed to modify the "data" of any node. You are also NOT allowed to create any new node. In other words, you have to modify links (next pointers) of nodes to sort the list.
- You MUST use a modified version of Selection sort to sort the nodes of the linked list.
 - In the 1st iteration, find the smallest node in the linked list, and move this node (do NOT swap nodes) to the start of linked list.
 - In the 2nd iteration, find the smallest node in the remaining portion of the linked list, and move (place) this node after the smallest node.

- \succ and so on...
- You are NOT allowed to create any temporary array (or linked list or any other data structure) to perform sorting

Post-Lab Activities

Task 01: Reverse Doubly LinkedList

1. void reverse()

Add this function to LinkedList class (ADT). This function should reverse the linked list, iteratively. Keep the following things in mind when implementing this function:

- You are NOT allowed to modify the "data" of any node. You are also NOT allowed to create any new node. So, the reversal is to be done by modifying the links (next pointers) of the nodes in the linked list.
- You are NOT allowed to create any temporary array (or linked list or any other data structure) to perform the reversal.
- The reversal is to be done in ONE traversal/pass (going from first node to the last node) through the linked list. You are NOT allowed to traverse the linked list more than once.

Submissions:

- For In-Lab Activity:
 - Save the files on your PC.
 - TA's will evaluate the tasks offline.
- For Pre-Lab & Post-Lab Activity:
 - Submit the .cpp file on Google Classroom and name it to your roll no.

Evaluations Metric:

• All the lab tasks will be evaluated offline by TA's

Division of Pre-Lab marks:	[40 marks]
 Task 01: Doubly LinkedList Implementation 	[40 marks]
Division of In-Lab marks:	[50 marks]
 Task 01: Add Functions to LinkedList Class 	[35 marks]
 Task 02: Combine Lists 	[15 marks]
Division of Post-Lab marks:	[20 marks]
 Task 01: Reverse LinkedList 	[20 marks]
	 Division of Pre-Lab marks: Task 01: Doubly LinkedList Implementation Division of In-Lab marks: Task 01: Add Functions to LinkedList Class Task 02: Combine Lists Division of Post-Lab marks: Task 01: Reverse LinkedList
